Where I can put my new Theorem of the Day

The web site www.theoremoftheday.org maintains a list of, say, L theorems. These are picked in turn to be displayed as 'Theorem of the Day'. To do this, a javascript function (written for me by Mike Child) measures the number of milliseconds since a fixed base date and divides this by 86400000, the number of milliseconds in twenty four hours. The result, rounded down, is a number of days, D, which increases by one every midnight. The theorem displayed on any given day is chosen as theorem number $D \pmod{L}$ in the list (indexed from 0 to $L-1$).

As often as possible I choose another classic theorem and add a description of it to the website; with respect to the above, this increases L to $L+1$, while D remains fixed. My problem is that I want to do this without the order of presentation of the theorems (and today's already chosen theorem in particular) being disturbed. So while adding the new theorem I have also to cycle the list of theorems round to bring position $D \pmod{L}$ into position $D \pmod{L+1}$.

Now the question is, how do I discover the current value of D? The answer I would like to give is that I use a scrupulously coded algorithm based on Dershowitz and Reingold's timeless Calendrical Calculations (Cambridge University Press, 2001). The reality is that I cheat: I increase the theorem array size by 1, upload the java code, observe what theorem is now (illicitly) occupying today's slot and make haste to re-upload with the correct theorem cycled into its rightful position.

However, in the process of pulling this fast one, I do get to find out the value of D; and it seems worth mentioning how because it is a nice illustration of one of the Theorems of the Day: the Chinese Remainder Theorem.

So, suppose that the day's theorem is currently in position s in the list, the value of $D \pmod{L}$, and that, when I add the new theorem, the current theorem changes to $D \pmod{L+1}$, which we notice is position t in the list. This is written as a pair of congruence equations in the unknown, D:

$$D \equiv s \pmod{L}, \qquad D \equiv t \pmod{L+1}. \tag{1}$$

Now the Chinese Remainder Theorem, in its simplest form, says that

$$x \equiv a \pmod{m}, \qquad x \equiv b \pmod{n},$$

where $\gcd(m,n)=1$, is solved, uniquely mod mn, by:

$$x = am(m^{-1} \pmod{n}) + bn(n^{-1} \pmod{m}), \tag{2}$$

where $m^{-1} \pmod{n}$ is the least positive multiple of m which has remainder $1 \pmod{n}$.

Now it is easy to see that $L^{-1} \pmod{L+1} = L$, since $L^2 = (L+1)(L-1)+1 \equiv 1 \pmod{L+1}$, and $(L+1)^{-1} \pmod{L} = L+1$, since $(L+1)^2 = L^2+2L+1 \equiv 1 \pmod{L}$. So equation (1) is solved by

$$\begin{aligned} D &= s(L+1)((L+1)^{-1} \pmod{L}) + tL(L^{-1} \pmod{L+1}) \pmod{L(L+1)} \\ &= s(L+1)^2 + tL^2 \pmod{L(L+1)} \end{aligned}$$

Example: suppose today's theorem is number 4 in the list of 42. I add a new theorem and now the theorem displayed has changed to number 16 (out of 43). Then

$$D = 4 \times 43^2 + 16 \times 42^2 \ (\bmod\ 42 \times 43) = 35620 \ (\bmod\ 1806) = 1306.$$

A doubt remains in my mind: is there not some clever way to find out the value of D without making today's theorem temporarily change? Perhaps instead of increasing L to $L+1$ some other increased length L' would reveal D without changing from theorem s to t (L' does not have to be coprime to L; provided $s \equiv t \pmod{\gcd(L, L')}$ an extended version of the Chinese Remainder Theorem still applies.) Or there is some other approach I have not thought of.
